(54) Personal computer peripheral device adapter

(57) An adapter to connect either Type I or Type II cards into a PCMCIA compliant PC Card interface on a

personal computer. A protective shutter mechanism receives both Type I and Type II cards.

FIG. 1C

Description

BACKGROUND

[0001] The invention relates to adapters for connecting devices to personal computers.

[0002] To expand the capacity and functional capability of portable laptops, computers, and other types of electronic devices, manufacturers developed "plug-in" peripheral cards containing circuits and devices such as memories and modems.

[0003] Because of the many possible methods of constructing the interface between a computer and a peripheral card device, standards were developed by the Personal Computer Memory Card International Association ("PCMCIA"), Japan Electronic Data Interchange Council ("JEDIC"), International Organization for Standardization ("ISO"), Compact Flash Association ("CFA"), and others. Standards for PC Cards (formerly called PCMCIA Cards) require that they have a length of approximately 85 mm, a width of 54 mm, and a maximum thickness of 5 mm.

[0004] For example, U.S. Patent No. 5,490,891 (the '891 Patent), incorporated herein by reference, discloses a housing for such a PC card, and a process for making same. The housing disclosed in the '891 Patent meets standards defined in the PCMCIA CompactFlash Specification Revision 2.1.1, incorporated herein by reference.

[0005] Following the introduction of PC cards, small flash memory devices, often referred to as CompactFlash™ cards, were introduced for use with personal electronic products, such as digital cameras and cellular phones. In keeping with the trend of developing smaller devices, CompactFlash cards were even smaller in size than PC Cards. One format for CompactFlash cards was promulgated by the CFA. A card with this format, which will be referred to as a Type I card, has an approximate length of 36 mm, an approximate width of 42 mm, and an approximate thickness of 3.3 mm. Type I cards were originally intended for use with products other than personal computers. Therefore, to connect a Type I card to a personal computer, an adaptor providing a PCMCIA interface at one end and an interface for the Type I card at the other end is used. These adapters will be referred to as Type I adapters. The Type I adapter plugs into the personal computer interface for PC Cards and the Type I card plugs into the Type I adapter.

[0006] More recently, a new format for CompactFlash cards that differs from the form factor of a Type I card has been proposed. A card with this new format, which will be referred to as a Type II card, has the same width and length as a Type I card but is thicker than the Type I card. In fact, Type II cards are as thick as PC Cards and Type I Adapters. Due to its thickness, the Type II card does not fit inside a standard PC Card housing or a Type I adapter. Consequently, the Type II card cannot be used with the Type I adapters currently used with

Type I cards.

[0007] It may be noted that the position of the Type II card socket holes and pins with respect to the bottom of the card is the same as that for the Type I card. Therefore, the Type II card's socket holes are offset from its center toward the bottom of the card on account of the Type II card's increased thickness.

[0008] Type II cards have grooves, approximately 1.0-1.2 mm deep, 36.4 mm long, and 1.7 mm high, running along the two side walls that correspond to the grooves running along the side walls of the Type I card. The grooves on the Type II card are offset toward the bottom of the card.

[0009] Standards covering the Type II card have been proposed. These proposed standards require that Type II cards have a thickness of no more than 5 mm, and that the center line of the holes be approximately 1 mm above the bottom of the Type II card.

SUMMARY

[0010] The invention provides an adapter configured to connect both Type I and Type II cards into a PCMCIA compliant PC Card interface on a personal computer.

More specifically, the invention provides a protective shutter mechanism adapted to receive both Type I and Type II cards.

[0011] In one aspect, the invention is directed to an apparatus comprising a header and a shutter. The header has a front face, two side walls extending from the header front face, and male connector pins extending from the header front face substantially parallel to the side walls. The inner surface of each side wall includes a guide rail. The shutter has a front face, a rear face, two sides with grooves slidably engaging the guide rails, a planar sheet projecting from an edge of the shutter rear face, and a plurality of holes extending from the shutter front face to the shutter rear face and corresponding to the male connector pins.

[0012] Implementations of the invention may include the following. A connector pin may be secured to the shutter and may extend through and slidably engage an aperture through the header. The planar sheet may include a lip to limit forward motion of the shutter by engaging the header, and the lip may be located on a tab extending from the planar sheet. A spring may bias the shutter away from the header. The holes in the shutter may be offset from the center toward the bottom of the shutter. A shroud may be connected to the shutter opposite the planar sheet, and a flange may run along a top and a bottom of the shutter front face. The apparatus may also include a frame having opposing side rails forming a bay at one end, a female connector disposed in an end of the frame opposite the bay, and an electrical connection between the female connector and the male connector pins in the header. The header may be disposed between the bay and the female connector, and the holes of the shutter may face the bay. The female

and male connectors may conform to PCMCIA standards.

[0013] In another aspect, the invention is directed to a dual mode adapter comprising a female connector, a male connector having a plurality of pins, an electrical connection between the female connector and the male connector, a shield for covering the pins in the male connector, and a housing for supporting the female connector, male connector and shield. The shield has a planar sheet with a lip and a plurality of holes corresponding to the pins in the male connector and is slidably engaged to the male connector. The housing defines a bay at the end of the adaptor opposite the female connector.

[0014] In another aspect, the invention is directed to a kit comprising a header and a shutter. The header has a front face, two side walls extending from the header front face, and male connector pins extending from the header front face substantially parallel to the side walls. The inner surface of each side wall includes a guide rail. The shutter has a front face, a rear face, two sides with grooves configured to slidably engage the guide rails, a planar sheet projecting from an edge of the shutter rear face, and a plurality of holes extending from the shutter front face to the shutter rear face and corresponding to the male connector pins.

[0015] In another aspect, the invention is directed to an apparatus for adapting a CompactFlash compatible electronic device to a PCMCIA compatible male connector. The apparatus comprises a PCMCIA compatible female connector, a CompactFlash compatible male connector, an electrical connection between the female connector and the male connector, and a housing supporting the male connector and the female connector. The housing has a top, a bottom, and a thickness between the top and the bottom that is essentially the maximum thickness that complies with the PCMCIA standard, and the male connector has pins arranged and the housing is configured to enable connection of either a type 1 or a type 2 CompactFlash electronic device to the male connector.

[0016] Implementation of the invention may include the following. The housing may include a bay which spans the full thickness of the housing and which spans enough of the width of the housing to accommodate the width of a CompactFlash-compatible electronic device. A CompactFlash Type 1-compatible or Type-2 compatible electronic device may be held fully within the bay, the CompactFlash device having a female connector mated with the male connector. The apparatus may include a shutter movable relative to the housing from a first position in which the pins are exposed for connection to a female connector to a second position in which the pins are protected.

[0017] In another aspect, the invention is directed to an apparatus comprising a connector assembly and a housing for the connector assembly. The connector assembly is configured to enable connection of either a type 1 or a type 2 CompactFlash electronic device to a

PCMCIA compatible interface of a personal computer, and the housing has a top, a bottom, and a thickness between the top and the bottom that is essentially the maximum thickness that complies with the PCMCIA standard.

[0018] Among the advantages of the invention are one or more of the following. The dual mode adapter can be used with both Type I and Type II cards. The dual mode adapter shutter protects the male connector pins from damage when they are not engaged. The shutter and its locking mechanism are an integrated unitary piece, and as such, the dual mode adapter contains few parts and is unlikely to break. The dual mode adapter is easily and economically manufactured. The dual mode adapter is inexpensive, yet provides sufficient structural integrity in an aesthetically pleasing package.

[0019] Other features and advantages of the invention will become apparent from the following description and from the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] Fig. 1A is a top view of an assembled dual mode adapter.

[0021] Fig. 1B is a side view of an assembled dual mode adapter.

[0022] Fig. 1C is an exploded perspective view of a dual mode adapter.

[0023] Fig. 1D is a perspective view, partially cross-sectional, of an assembled dual mode adapter.

[0024] Fig. 2 is a detailed view of the header.

[0025] Fig. 3 is a detailed view of one embodiment of the shutter.

[0026] Fig. 4 is a detailed view of another embodiment of the shutter.

DETAILED DESCRIPTION

[0027] Referring to Figures 1A-1D, a dual mode adapter 10 has two covers 101, 102, a frame 103 having a bay 104, a female connector 105, a header 106 having male connector pins 107, an electrical connection 108 between female connector 105 and header 106, a shutter 109, and two compression springs 110. When assembled, dual mode adapter 10 has a width and height conforming to PCMCIA standards set for PC Card devices. Namely, as assembled, the adapter has a length of approximately 85 mm, a width of approximately 54 mm, and is no more than approximately 5 mm thick.

[0028] As shown in Figure 1C, covers 101, 102 may be substantially rectangular in shape and may be stamped from metal or formed from plastic material. The covers 101, 102 serve to protect the internal components of dual mode adapter 10. Covers 101, 102 are connected to frame 103 along their longer sides. In one embodiment, frame 103 includes two opposing side rails 117 to hold covers 101, 102 together. In another embodiment, side rails 117 of frame 103 may be held together

by a pair of ribs (not shown) that intersect side rails 117 at an angle.

[0029] Frame 103 serves to hold covers 101, 102 together and support female connector 105, electrical connection 108, header 106, and shutter 109 between covers 101, 102. Side rails 117 of frame 103 form bay 104 in the front half of dual mode adapter 10. The dimensions of bay 104 are such that a Type I or Type II card conforming to CFA standards can slide into bay 104 and connect to header 106 through shutter 109. The frame 103, side rails 117 and ribs, if present, may be a unitary body formed from any suitable material.

[0030] Female connector 105 conforms to PCMCIA standards and is located at the end of the assembled dual mode adapter opposite bay 104. The outer face 123 of female connector 105 is rectangular and has holes 118 complying with PCMCIA standards to attach the dual mode adapter to a personal computer. The top and bottom edges of the outer face of female connector 105 each have a flange 119. When assembled, the edges of covers 101, 102 meet flanges 119 to encase all of female connector 105 except holes 118 in the body of dual mode adapter 10. This protects users from the sharp edges of covers 101, 102. The inner face of female connector 105 is electrically coupled to header 106 by electrical connection 108. Electrical connection 108 may be formed by any suitable medium, such as a printed circuit board (illustrated) or cables (not shown).

[0031] With reference to Figure 2, header 106 has a rectangular front face 201 and two side walls which extend perpendicularly from the edges of front face 201 toward bay 104. Male connector pins 107 (only a representative sample of pins is shown), which conform to PCMCIA standards, project from front face 201 toward the front end of dual mode adapter 10. The side walls 111 are parallel to and longer than the male connecting pins. The inner surface of each side wall 111 has a guide rail 112. In addition, a knob 113 may extrude from the outer surface of each side wall 111 to fit within a corresponding slot 120 in frame 103 (see Figure 1C).

[0032] Header 106 also includes two header apertures 202 (only one is shown in this perspective view) that extend from front face 201 to the back face of header 106. One aperture is located between male connector pins 107 and each side wall 111. Once the dual mode adapter is assembled, header 106 is located in the mid-section of frame 103 with male connection pins 107 facing bay 104 and its back face attached to electrical connector 108. Header 106 may be a unitary piece made of plastic material.

[0033] With reference to Figure 3, shutter 109 is generally rectangular in shape. A thin flange 303 runs along the top and bottom edges of a front surface 304 of the shutter. When dual mode adapter 10 is assembled and a CompactFlash card is connected, covers 101, 102 are placed against flanges 303 to encase shutter 109 and protect consumers from the sharp edges of covers 101, 102.

[0034] The shutter 109 includes two grooves 301 which run along the outer surface of each side 306 of shutter 109. Grooves 301 mate with header guide rails 112 to slidably connect shutter 109 to header 106 (see Figure 1C). In addition, two shutter apertures 302 are formed in a back face 305 of the shutter, and may extend through the shutter to the front face 304.

[0035] Returning to Figure 1C, two connector pins 116 are attached to shutter 109 and extend toward the back of the dual mode adapter. The connector pins 116 may be inserted into and frictionally secured in two shutter apertures 302. When shutter 109 is slidably connected to header 106 so that connector pins 116 extend into header apertures 202. The header apertures 202 are wider than connecting pins 116 so that connecting pins 116 slidably engage header 106. The compression springs 110, which are held in place by connector pins 116, bias shutter 109 away from front face 201 of header 106.

[0036] Shutter 109 also includes holes 121, corresponding in number and location with male connector pins 107, which extend through the shutter body from front face 304 to back face 305. In one embodiment, holes 121 may be offset from the center of shutter 109. For example, the center line of the bottom row of holes 121 may be approximately 1 mm above bottom surface 305. With this offset, both Type I and Type II cards can be used with the dual mode adapter 10. This offset, however, may not be required for other embodiments. Holes 121 are spaced to coincide with male connector pins 107 when shutter 109 and header 106 are engaged.

[0037] A relatively thin planar sheet 114 is connected to the top back edge of shutter 109. A lip 115 extends along a rim of planar sheet 114. Shutter 109, including holes 121, planar surface 114, flanges 303 and grooves 301, may be an integrated unitary piece formed from plastic material.

[0038] When bay 104 is empty, compression springs 110 urge shutter 109 into its forwardmost position so that planar sheet 114 covers and protects male connector pins 107. When a Type I or II card is inserted into bay 104, shutter 109 is forced back so that planar sheet 114 slips between cover 101 and electrical connection 108 and male connector pins 107 extend through holes 121 to engage the card. When the Type I or II card is removed, compression springs 110 force shutter 109 forward over male connector pins 107. The lip 115 engages the bottom rear edge of header 106 to limit the forward motion of shutter 109 and lock the shutter in place (see Figure 1D). When shutter 109 is in its forwardmost position, the tips of male connector pins 107 are protected by the body of shutter 109, and planar sheet 114 covers one side of the unengaged male connector pins 107.

[0039] As shown in Figure 3, lip 115 may be located along the edge of planar sheet 114. Alternately, as shown in Figures 1B and 1D, the planar sheet may include two tabs 122 that project toward header 106. Each tab has a lip 115 along the edge of the tab.

[0040] Figure 4 illustrates an embodiment of the shutter that includes a shroud 401. The shroud 401 is connected to the lower edge of shutter 109 and is disposed in a generally parallel arrangement with planar sheet 114. Shroud 401 is very thin and may be formed of nylon, Mylar, standard or engineering grade thermal plastic material, thermoset material, or the like. When a Type I or II card is inserted into bay 104, springs 116 are compressed and shutter 109 and shroud 401 slide toward header 106 so that shroud 401 slips between cover 102 and electrical connection 108. The motion of shutter 109 stops when the rear face of shutter 109 contacts the front face of header 106. When the card is removed and shutter 109 is urged by compression springs 110 into its forwardmost position, shroud 401 slides out to cover and protect the side of male connector pins 107 opposite planar sheet 114.

[0041] Although Type II cards are thicker than Type I cards, either a Type I or Type II card can fit in the bay 104 formed by frame 103. In addition, since the location of the connection socket with respect to its bottom surface is the same for both Type I and Type II cards, both Type I and Type II cards will engage the offset male connector pins which extend through the offset holes in the shutter. Thus, dual mode adaptor 10 is capable of connecting to either a Type I or Type II card and conforms to PCMCIA standards.

[0042] Other embodiments are within the scope of the following claims. For example, the embodiments disclosed in the figures and discussed above show an dual mode adapter and shutter mechanism conforming to the standards of the CFA. However, some aspects of the invention may apply to dual mode adapters for other small-format devices, including for example, those complying with the standards of PCMCIA, JEDIC, ISO, and others. The embodiments illustrated in the figures use springs to push the shutter forward when male connector pins are not engaged. However, other resilient materials may be used to bias the shutter away from the header. Components may be joined by sonic welding, with adhesives, by the application of heat, by chemical reaction, or by any other suitable method. Adhesives useful for joining the components include, for example, thermosetting resins and thermoplastic resins. Further, dual mode adapter components may be constructed of a variety of injection molded plastic materials including, for example, thermoplastic resins such as polycarbonate, acrylic and others, and thermosetting resins such as epoxy, silicone, and others. In each case, care is to be taken to choose compatible materials for parts to be joined and the joining system.

Claims

1. An apparatus comprising:

a header having a front face, two side walls ex-

tending from the header front face, and male connector pins extending from the header front face substantially parallel to the side walls, the inner surface of each side wall including a guide rail; and

a shutter having a front face, a rear face, two sides with grooves slidably engaging the guide rails, a planar sheet projecting from an edge of the shutter rear face, and a plurality of holes extending from the shutter front face to the shutter rear face and corresponding to the male connector pins.

2. The apparatus of claim 1, further comprising a connector pin secured to the shutter and extending through and slidably engaged with an aperture in the header.

3. The apparatus of claim 1, wherein the planar sheet includes a lip to limit forward motion of the shutter by engaging the header.

4. The apparatus of claim 1, further comprising a spring for biasing the shutter away from the header.

5. The apparatus of claim 1, wherein the holes in the shutter are offset from the center toward the bottom of the shutter.

6. The apparatus of claim 1, wherein the shutter includes a shroud connected opposite the planar sheet.

7. The apparatus of claim 1, further comprising:

a frame having opposing side rails forming a bay at one end;

a female connector disposed in an end of the frame opposite the bay; and

an electrical connection between the female connector and the male connector pins in the header;

wherein the header is disposed between the bay and the female connector; and

wherein the holes of the shutter face the bay.

8. A dual mode adapter comprising:

a female connector;

a male connector having a plurality of pins;

an electrical connection between the female connector and the male connector;

a shield to cover the pins in the male connector, the shield having a planar sheet with a lip and a plurality of holes corresponding to the pins in the male connector, the shield slidably engaged to the male connector; and

a housing to support the female connector,

male connector and cover piece, the housing defining a bay at the end of the adaptor opposite the female connector.

9. A kit comprising:

a header having a front face, a rear face, two side walls extending from the header front face, and male connector pins extending from the header front face substantially parallel to the side walls, the inner surface of each side wall including a guide rail; and

a shutter having a front face, a rear face, two sides with grooves configured to slidably engage the guide rails, a planar sheet projecting from an edge of the shutter rear face, and a plurality of holes extending from the shutter front face to the shutter rear face and corresponding to the male connector pins.

10. An apparatus for adapting a CompactFlash compatible electronic device to a PCMCIA compatible male connector comprising:

a PCMCIA compatible female connector;
a CompactFlash compatible male connector;
an electrical connection between the female connector and the male connector; and
a housing supporting the male connector and the female connector, the housing having a top, a bottom, and a thickness between the top and the bottom that is essentially the maximum thickness that complies with the PCMCIA standard;

wherein the male connector has pins arranged and the housing is configured to enable connection of either a type 1 or a type 2 CompactFlash electronic device to the male connector.

11. The apparatus of claim 10, wherein the housing includes a bay which spans the full thickness of the housing and which spans enough of the width of the housing to accommodate the width of a CompactFlash-compatible electronic device.

12. The apparatus of claim 11, further comprising a CompactFlash Type 1-compatible electronic device held fully within the bay, the CompactFlash Type 1-compatible device having a female connector mated with the male connector.

13. The apparatus of claim 11, further comprising a CompactFlash Type 2-compatible electronic device held fully within the bay, the CompactFlash Type 2-compatible device having a female connector mated with the male connector.

14. The apparatus of claim 11, further comprising a

shutter movable relative to the housing from a first position in which the pins are exposed for connection to a female connector to a second position in which the pins are protected.

15. An apparatus comprising:

a connector assembly configured to enable connection of either a type 1 or a type 2 CompactFlash electronic device to a PCMCIA compatible interface of a personal computer; and
a housing for the connector assembly, the housing having a top, a bottom, and a thickness between the top and the bottom that is essentially the maximum thickness that complies with the PCMCIA standard.

CLAIMS INCURRING FEES

The present European patent application comprised at the time of filing more than ten claims.

- ☐ Only part of the claims have been paid within the prescribed time limit. The present European search report has been drawn up for the first ten claims and for those claims for which claims fees have been paid, namely claim(s):
- ☐ No claims fees have been paid within the prescribed time limit. The present European search report has been drawn up for the first ten claims.

LACK OF UNITY OF INVENTION

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

see sheet 8

- ☐ All further search fees have been paid within the fixed time limit. The present European search report has been drawn up for all claims.
- ☐ As all searchable claims could be searched without effort justifying an additional fee, the Search Division did not invite payment of any additional fee.
- ☐ Only part of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the inventions in respect of which search fees have been paid, namely claims:
- ☒ None of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the invention first mentioned in the claims, namely claims:

1-9

European Patent
Office

**LACK OF UNITY OF INVENTION
SHEET B**

Application Number
EP 99 30 0887

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

1. Claims: 1-9

An apparatus comprising a header and a shutter.

2. Claims: 10-15

An apparatus that enables connection of either a type 1 or a type 2 CompactFlash electronic device to a PCMCIA compatible interface.

**ANNEX TO THE EUROPEAN SEARCH REPORT
ON EUROPEAN PATENT APPLICATION NO.**

EP 99 30 0887

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report. The members are as contained in the European Patent Office EDP file on
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
